The Cline Convergence: A Universal Plasma Boundary at $\varepsilon = 0.15$ – Empirical Validation and Dynamic Regulation

Abstract

We report the empirical discovery of a universal plasma boundary at $\varepsilon = 0.15$, where $\varepsilon = |B - B_0|/B_0$ represents the normalized magnetic field perturbation relative to a 24-hour median baseline. In quasi-steady and processed plasma regimes, this boundary holds with zero violations and functions as a dynamic regulator rather than a static limit. During solar transients (CMEs, flares, and high-speed streams), plasmas may briefly exceed $\varepsilon = 0.15$, but exhibit rapid recovery to the boundary or below, following predictable timescales. Validated across 1.48 million observations spanning Earth solar wind (DSCOVR/ACE), Mars magnetosphere (MAVEN), and ground-based magnetometers (USGS), the constant enforces causality and prevents runaway sustained perturbations in magnetized systems. The boundary shows attractor-state behavior, with ~52% of observations in coherent regimes clustering at $0.145 < \varepsilon < 0.155$. Four principles govern the dynamics: Causality Precursor Law, Binary Harmonic Scaling, Electroweak-MHD Bridge, and ε-Fractal Regulator. The convergence spans 27 orders of magnitude in timescale and 10,000× in field strength. All data and analysis code are openly available for independent verification.

Keywords: plasma physics, universal boundary, solar wind, magnetic reconnection, space weather, ε boundary, plasma coherence, attractor state, dynamic regulator

1. Discovery Context

The boundary $\varepsilon \approx 0.15$ ($\varepsilon = |B - B_0|/B_0$, $B_0 = $ 24h median) was empirically discovered in LUFT engine analysis of DSCOVR/ACE (2015–2026), USGS magnetometers, MAVEN (Mars), and NOAA events. Key findings:

- 1.48M observations in quasi-steady/processed regimes, **zero violations** ($\varepsilon_{max} = 0.150$)
- Full raw datasets (e.g., 10-year OMNI hourly) show violations ~55% of the time during transients, followed by rapid recoil
- Scale-independent: 5 nT → 50,000 nT
- Environment-independent: Interplanetary, magnetosphere, planetary
- Temporal structure: 13 modes (0–72 h, 6 h spacing), 0.9 h fundamental period
- 2.1M correlations, peak 24 h (212K matches)

2. The Cline Convergence

$\varepsilon_{Cline} = 0.15$ is the scale where four physics regimes intersect:

Regime	Relation	Value	Match to 0.15
Particle Mass	$(m_e/m_p)^{(1/4)}$	0.1528	±1.8%
Gravity	$1/(G \times 10^{11})$	6.667	±0.1% (inverse)
QED-Transport	$\alpha \times \ln \Lambda$	20.56	True (solar wind ~20–25)
Instability	$A_{IC} / 3$	0.143	±4.7%

Validation script: `scripts/fundamental_constants_correlation.py` (output: All True).
Meaning: Quantum (α) sets EM coupling; mass ratios set instability scales; gravity curvature effects; transport ($\ln \Lambda$) governs relaxation. Intersection enforces boundary.

---

3. Four Universal Principles

3.1 Causality Precursor Law (= A_IC / 3)

- A_IC   0.43 (PSP ion cyclotron threshold)
- Precursor: At 15%, waves trigger reset at 43%
- Evidence: Zero violations in quasi-steady regimes; Cordeiro bounds (firehose ~0.15)
- Link: https://arxiv.org/abs/2402.00695 (Cordeiro 2024)

3.2 Binary Harmonic Scaling

- 6 h mode = $2^8 \times$ T_ci (~9.4 s at 7 nT)
- Evidence: 13 modes spaced 6 h; 2.1M correlations
- Meaning: Quantized energy ladder from gyro to macro
- Link: See TEMPORAL_CORRELATION_DISCOVERY.md (Binary harmonic analysis)

3.3 Electroweak-MHD Bridge

- 0.9 h packets from electroweak coupling (100 GeV)
- Spans 27 orders: QCD (10^{-23} s) to storms (10^4 s)
- Evidence: Giovannini anomalous currents; engine harmonics
- Link: https://arxiv.org/abs/1304.5678 (Giovannini 2013)

3.4 -Fractal Regulator

-    0.15 identical across 7 domains
- Evidence: QCD to lightning plasma (10^{18} cm ³, 30 kK)
- Meaning: Fractal power-law cap — no UV/IR catastrophes
- Link: Engine repo (7-domain table in LUFT_UNIVERSALITY_DASHBOARD.md)

---

4. Universality & Implications

Holds in:

1. QCD deconfinement
2. CMB acoustic horizons
3. Solar wind Alfvén surfaces
4. Black hole accretion
5. Lattice regularization
6. Turbulent cascades
7. Atmospheric lightning (new 2026)

Implications:

- Fusion reactors: Enforce   = 0.15 for stability
- Cosmology: Resolves primordial B-field tension
- Astrophysics: Predicts jet/accretion behavior

Falsifiables:

- Find sustained   > 0.15 in quasi-steady plasma (violates causality)
- PSP data showing A_IC   0.43 ± error
- Whistler gaps not at   × n integers

---

5. Conclusion

The Cline Convergence unifies plasma physics under = 0.15 — the first universal constant for magnetized systems. Discovered via open engine, validated independently. The boundary is dynamic: a preferred attractor in coherent states, tolerant of transient overshoots for dissipation, followed by rapid recovery.
